OpenAI's ChatGPT Image Creator (DALL·E 3 in ChatGPT) & Sora (Text-to-Video)

What it is: In ChatGPT (with Plus), OpenAI has integrated its latest **DALL·E 3** image generator. You can simply ask ChatGPT to create an image, and it will produce one within the chat. This model is very advanced in following detailed prompts accurately and can even generate legible text in images (like signs, logos, etc., which older models struggled with). **Sora** is OpenAI's *text-to-video* model (available to some ChatGPT users) – essentially "DALL·E for video" – which produces short video clips up to ~20 seconds with no sound.

How to use (ChatGPT Image/DALL·E): Just instruct ChatGPT with a prompt like *"Create an image of …"* and optionally specify style or format. Since it's conversational, you can refine the image by telling ChatGPT what to change or keep in subsequent messages. This multi-turn refinement is a unique strength: you can generate an image, then say "make it brighter" or "now change the background to a beach" and it will do it, maintaining context (for example, keeping the same character or layout).

- **Prompting DALL·E 3 in ChatGPT:** Be clear and descriptive. This model shines at **precision** and using its broad knowledge. You can include quite intricate scenarios. *Example prompt: "Create an illustration for a Reel: a **cute corgi** riding a skateboard in a park. Late afternoon sun for golden light, in a **Pixar-like cartoon style**. The corgi wears sunglasses. Include motion lines or a blur to show speed."* This would likely yield a fun, high-quality image. DALL·E 3 understands a lot of specifics (like styles or even references to famous characters or art, within content guidelines). Always specify **aspect ratio** if you need – however, within ChatGPT you might not have a direct "--ar" parameter. Instead, you can say "portrait orientation" or "vertical layout" in the prompt, and it usually respects that.

- **Advantages:** DALL·E 3 (ChatGPT image) is great at **coherent details** and following complex instructions. It also can use the **chat context** – for example, if you've been talking about a certain character or script earlier in the chat, you can say "Create an image of that scene" and it knows the context. This is extremely useful for storyboarding: discuss a scene with ChatGPT, then just ask for an image of it. It tends to produce aesthetically pleasing art with minimal tweaking.

- **Limitations:** The image generation may have some guardrails (it won't produce disallowed content or certain styles). And you don't have manual controls like seeds or steps. You get 4 variations typically and can regenerate if needed. Also, each image is static – for video, you'd use Sora.

Using Sora (Text-to-Video): Sora is accessed through ChatGPT (when enabled) or possibly a separate interface. You simply describe the video you want, similar to an image prompt. It generates short video clips (up to ~20 seconds, 1080p). It can handle **multiple characters, moving objects, and camera motions** in a scene. However, videos might look a bit surreal or game-like and they **do not have audio** – you'd add music or sound effects in post.

- **Sora Prompt Tips:** Describe the scene *and the movement*. For example: *"A 15-second video: a **travel vlogger** walking through a crowded market in Morocco. The camera follows behind her (over-the-shoulder view) and then pans around to her face as she smiles at the colorful surroundings. **Natural lighting**, bustling atmosphere. No audio."* This prompt gives an idea of camera work ("follows behind" and "pans around"), subject action, and setting. Sora will attempt to create that continuous shot. You can also specify *camera types* (e.g. "drone shot over a beach" or "handheld camera feel, shaky"). Including such terms can influence the style of motion.

- **Leverage image input:** Sora can take an image and animate it or extend a video. For instance, you could give it a photo of a person and prompt it to make the person wave, or give a landscape photo and have it animate moving clouds. This can produce more consistent subjects. If you have a key image (like your brand character or a specific person), this feature is gold for creating quick video clips with them.

- **Example Sora prompt:**
  *"Create a **10-second video** of a **sports car** driving through downtown at night. The camera starts with a wide shot of the city skyline, then **zooms in** and **tracks** the red sports car as it speeds by. Neon signs blur with motion. (No sound needed)."*
  This instructs Sora on the sequence (establishing wide shot then zoom and track), the subject (red sports car), and the vibe (neon night city, motion blur for speed). Sora would generate a clip with those elements, and you'd have a nice dynamic B-roll for a Reel.

- **Note:** Because Sora is new, expect some quirks. The "physics" might be off (e.g. objects merging weirdly), and highly complex movements might not perfectly execute (some Reddit users noted it can ignore some movement prompts at times). Keep prompts simple and focus on one primary action or camera move for best results. And since it's limited to seconds, plan to use multiple clips for longer videos (we'll cover editing in movement section).
