Character consistency is what separates “random AI scenes” from a recognizable visual video.

In the case of the Skeleton, consistency is relatively easy.

Why?

Because your **image references already contain the base character design**.

Nano Banana understands the skeleton’s core anatomy and structure from those references.

The only things you need to define manually in each Nano prompt are:

- The outfit (based on the script’s time period or scenario)
- Any added elements (hair, glasses, accessories, armor, props etc.)

As long as:

- Your references remain consistent
- Your outfit descriptions are clear

The Skeleton will stay visually stable.

How Image References Actually Work

Image references do not “copy” images - they guide the model (unless your prompt is similar to your image references then yes, Nano Banana will copy them [see more in 6.3 Repetitive Generations Issue]).

They tell Nano Banana what should stay consistent across generations.

However, what many people don’t realize is that **what you include in the reference matters just as much as what you exclude.**

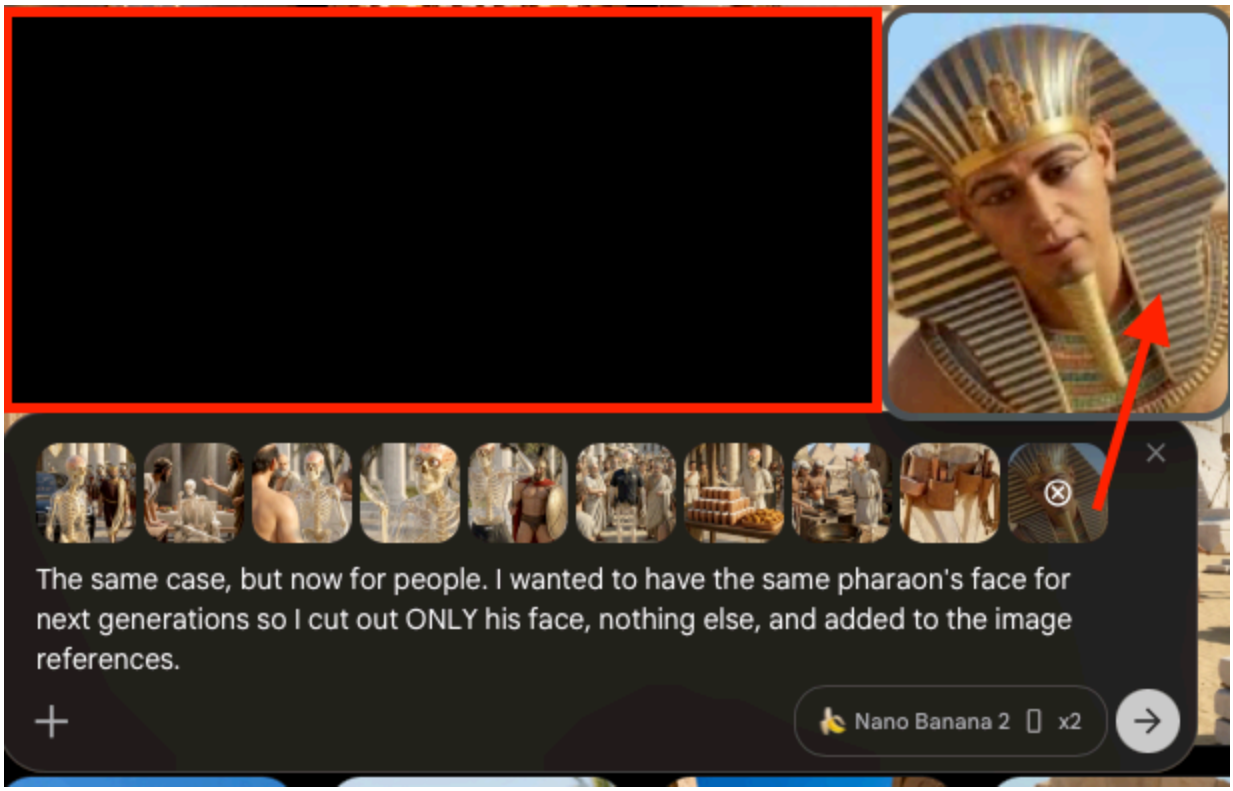

If you upload a full image as a reference, Nano may start recreating not just the character, but also:

- the background
- the lighting
- the composition

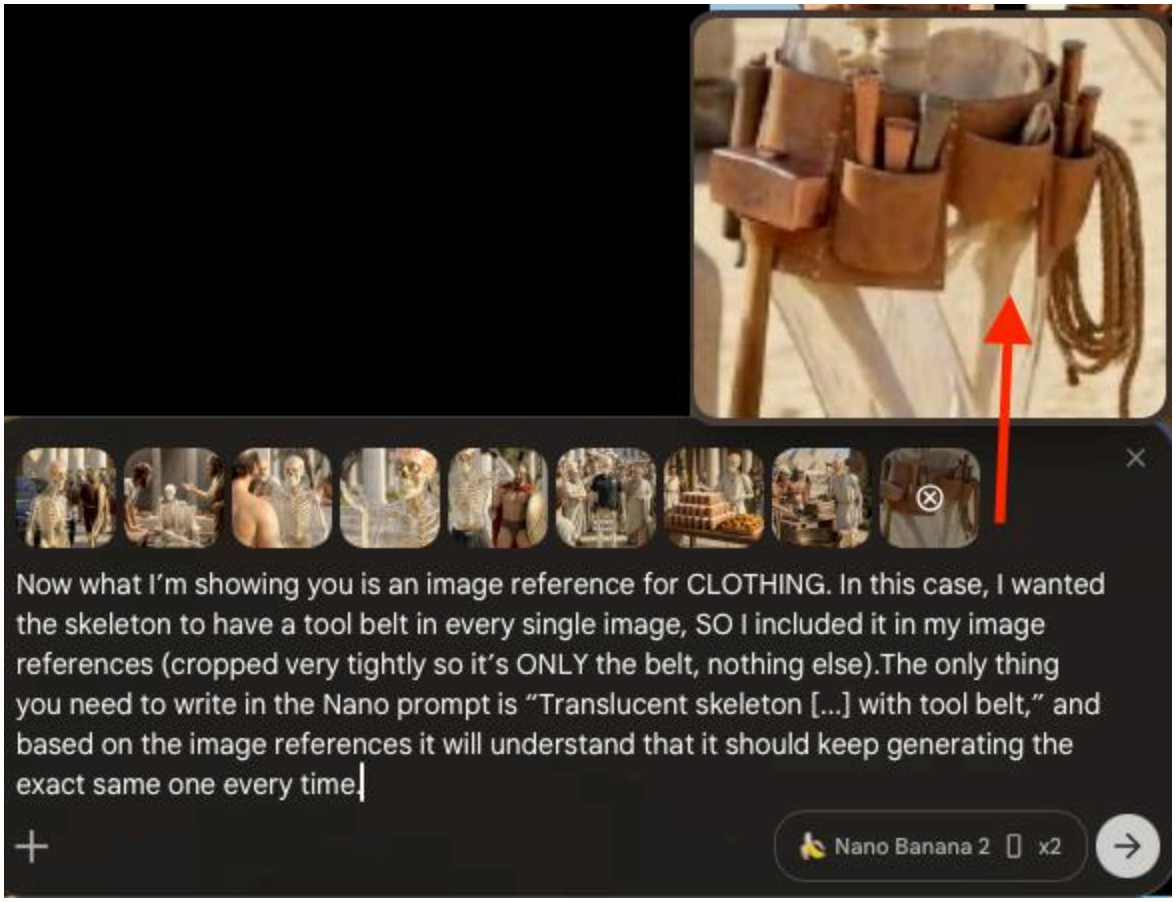

This is why, for consistency, you should isolate only the element you want to repeat.

For example:

- Outfit consistency → crop only the clothing
- Face consistency → crop only the face

- Accessory consistency → crop only the accessory

This prevents Nano from copying entire scenes and instead focuses it on the specific feature you want to preserve.

The Real Problem: Other Characters

The difficulty appears when you introduce additional characters.

For example:

- A woman standing next to the skeleton
- A soldier
- A merchant
- A king
- A child
- A crowd

Without control, these characters can change appearance between scenes.

So how do you maintain consistency?

It’s simple.

You use image references again.

Step-by-Step: Maintaining Side Character Consistency

Let’s say your script introduces a woman next to the skeleton.

1. First, generate a scene with:
    - The Skeleton
    - The Woman
2. Download that image **AND CROP ONLY THIS WOMAN FROM IT.**
3. Add that cropped image to your **image references section**.

Now, when you generate the next scene and mention the same woman again in the prompt:

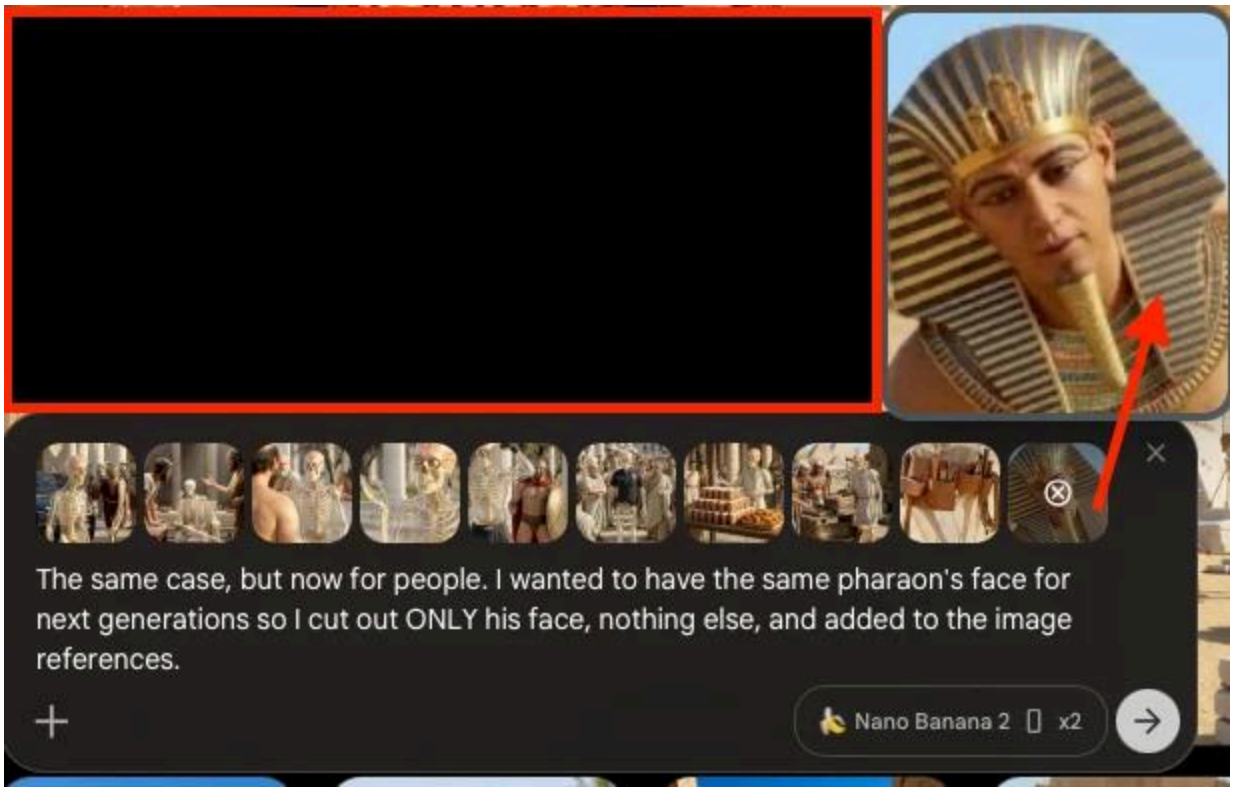

Nano Banana will reference the uploaded image and recreate her with the same facial structure, hair, clothing style and overall appearance.

For example:

Scene 1:
Skeleton + woman in marketplace → generate → download → add to references.

Scene 2:
Skeleton + woman in different location or pose → Nano pulls from image references → same woman, new angle.

This keeps visual continuity.

This Also Applies to Locations

The same principle works for environments (**but use it carefully**, as it can generate EXACTLY the same background as in the image references).

If you generate:

- A specific medieval street
- A specific marble temple courtyard
- A specific desert battlefield

Download that image and add it to your references.

In future prompts, describe the same location clearly.

Nano Banana will use your reference image to maintain environmental consistency.

In short:

Skeleton consistency → controlled through base image references + outfit clarity.
Side character consistency → controlled by generating once, then reusing that generation as a reference.
Location consistency → same principle.
