One of the biggest mistakes with Nano Banana Pro is using image references that overlap too much with the prompt itself.

This causes repetitive generations.

Here's the rule:

Image references should teach the model the look of the character, people, clothing and overall visual style - not the exact environment of the scene.

For example, if your story takes place in ancient greece, then you should **not** include ancient greece background images in your image references (or include AT LEAST 5 different ones). **It's not always an ISSUE but if it is, just read it all.**

Why?

Because if both:

- the prompt says "ancient greece",
- and the references also show ancient greece,

Nano may rely too heavily on those references and begin recreating the same background again and again.

So in that case, remove ancient greece-based references and replace them with images that still match the style but do **not** repeat the same environment.

It could even be a completely different setting (like ancient egypt etc). The location itself should be described in the prompt, not taught through the reference images.

That means your image references should mainly communicate:

- how the main character looks,
- how other people look,
- the overall visual style,
- outfit consistency,
- face consistency.

The prompt should communicate:

- location,
- action,
- scene-specific details,
- moment-to-moment composition.

This separation makes Nano much more flexible and helps **avoid repetitive backgrounds.**

Another important point is image quality.

The references you use should be high quality, because Nano Banana Pro relies on them heavily. Poor quality references often lead to weaker final generations.

Also, sometimes the preview on desktop can make the images look softer or less sharp than they actually are. In many cases, this is not a real problem.

Once the visuals are moved into Kling/Veo3, edited properly and uploaded to YouTube or TikTok, they usually look much better in the final result than they do in raw desktop preview.

So if the image looks slightly soft during generation, that does not automatically mean it will look bad in the final video.

In most cases, if:

- the character looks good,
- the background looks good,
- and the scene composition works,

then the final edited result will still look very strong.
